SUMMARY

Coronaviruses make use of a large envelope protein called spike (S) to engage host cell receptors and catalyze membrane fusion. Because of the vital role that these S proteins play, they represent a vulnerable target for the development of therapeutics. Here, we describe the isolation of single-domain antibodies (VHHs) from a llama immunized with prefusion-stabilized coronavirus spikes. These VHHs neutralize MERS-CoV or SARS-CoV-1 S pseudotyped viruses, respectively. Crystal structures of these VHHs bound to their respective viral targets reveal two distinct epitopes, but both VHHs interfere with receptor binding. We also show cross-reactivity between the SARS-CoV-1 S-directed VHH and SARS-CoV-2 S, and demonstrate that this cross-reactive VHH neutralizes SARS-CoV-2 S pseudotyped viruses as a bivalent human IgG Fc-fusion. These data provide a molecular basis for the neutralization of pathogenic betacoronaviruses by VHHs and suggest that these molecules may serve as useful therapeutics during coronavirus outbreaks.

INTRODUCTION

Coronaviruses are enveloped, positive-sense RNA viruses that are divided into four genera (α, β, γ, δ) and infect a wide variety of host organisms (Woo et al., 2009). There are at least seven coronaviruses that can cause disease in humans, and four of these viruses (HCoV-HKU1, HCoV-OC43, HCoV-NL63 and HCoV-229E) circulate seasonally throughout the global population, causing mild respiratory disease in most patients (Gaunt et al., 2010). The three remaining viruses, SARS-CoV-1, MERS-CoV and SARS-CoV-2, are zoonotic pathogens that have caused epidemics or pandemics with severe and often fatal symptoms after emerging into the human population (Chan et al., 2020; Huang et al., 2020; Ksiazek et al., 2003; Lu et al., 2020; Zaki et al., 2012). For these highly pathogenic betacoronaviruses, prophylactic and therapeutic interventions are needed.

The surfaces of coronaviruses are decorated with a spike glycoprotein (S), a large class I fusion protein (Bosch et al., 2003). The S protein forms a trimeric complex that can be functionally categorized into two distinct subunits, S1 and S2, that are separated by a protease cleavage site. The S1 subunit contains the receptor-binding domain (RBD), which interacts with a host-cell receptor protein to trigger membrane fusion. The S2 subunit contains the membrane fusion machinery, including the hydrophobic fusion peptide and the α-helical heptad repeats. The functional host cell receptors for SARS-CoV-1 and MERS-CoV are angiotensin converting enzyme 2 (ACE2) and dipeptidyl peptidase 4 (DPP4), respectively (Li et al., 2003; Raj et al., 2013). The interactions between these receptors and their respective RBDs have been thoroughly characterized, both structurally and biophysically (Li et al., 2005; Wang et al., 2013). Recently, it has been reported that SARS-CoV-2 S also makes use of ACE2 as a functional host-cell receptor

23   and several structures of this complex have already been reported (Hoffmann, 2020; Lan, 2020;

24   Wan et al., 2020; Yan, 2020; Zhou et al., 2020).

25   Recent advances in cryo-EM have allowed researchers to determine high-resolution

26   structures of the trimeric spike protein ectodomains and understand how S functions as a

27   macromolecular machine (Kirchdoerfer et al., 2016; Li et al., 2005; Walls et al., 2016; Wang et

28   al., 2013). Initial cryo-EM characterization of the SARS-CoV-1 spike revealed that the RBDs

29   adopted at least two distinct conformations. In the "up" conformation, the RBDs jut out away

30   from the rest of S, such that they can easily engage ACE2 without steric clash. In the "down"

31   conformation, the RBDs are tightly packed against the top of the S2 subunit, preventing binding

32   by ACE2 (Gui et al., 2017). Subsequent experiments have corroborated this phenomenon and

33   similar dynamics have been observed in MERS-CoV S, SARS-CoV-2 S and in alphacoronavirus

34   S proteins (Kirchdoerfer et al., 2018; Pallesen et al., 2017; Walls, 2020; Wrapp and McLellan,

35   2019; Wrapp et al., 2020; Yuan et al., 2017). Due to the relatively low abundance of particles

36   that can be observed by cryo-EM with three RBDs in the up conformation, it is thought that this

37   conformation may correspond to an energetically unstable state (Kirchdoerfer et al., 2018;

38   Pallesen et al., 2017). These observations have led to the hypothesis that the CoV RBDs might

39   act as a molecular ratchet: a receptor-binding event would trap the RBD in the less stable up

40   conformation, leading to gradual destabilization of S1 until S2 is finally triggered to initiate

41   membrane fusion. Recent experiments characterizing RBD-directed anti-SARS-CoV-1

42   antibodies that trap the SARS-CoV-1 RBD in the up conformation and lead to destabilization of

43   the prefusion spike have lent support to this hypothesis (Walls et al., 2019).

44   Numerous anti-SARS-CoV-1 RBD and anti-MERS-CoV RBD antibodies have been

45   reported and their mechanisms of neutralization can be attributed to the occlusion of the

4

46 receptor-binding site and to trapping the RBD in the unstable up conformation, effectively acting

47 as a receptor mimic that triggers a premature transition from the prefusion-to-postfusion

48 conformation (Hwang et al., 2006; Walls et al., 2019; Wang et al., 2018; Wang et al., 2015). In

49 addition to conventional antibodies, camelids also produce heavy chain-only antibodies

50 (HCAbs), which contain a single variable domain (VHH) instead of two variable domains (VH

51 and VL) that make up the equivalent antigen-binding fragment (Fab) of conventional IgG

52 antibodies (Hamers-Casterman et al., 1993). This single variable domain, in the absence of an

53 effector domain, is referred to as a single-domain antibody, VHH or Nanobody® and typically

54 can acquire affinities and specificities for antigens comparable to conventional antibodies. VHHs

55 can easily be constructed into multivalent formats and they have higher thermal stability and

56 chemostability than most antibodies (De Vlieger et al., 2018; Dumoulin et al., 2002; Govaert et

57 al., 2012; Laursen et al., 2018; Rotman et al., 2015; van der Linden et al., 1999). VHHs are also

58 known to be less susceptible to steric hindrances that might prevent the binding of larger

59 conventional antibodies (Forsman et al., 2008). Their advantageous biophysical properties have

60 led to the evaluation of several VHHs as therapeutics against common respiratory pathogens,

61 such as respiratory syncytial virus (RSV) (Detalle et al., 2016; Rossey et al., 2017). The use of

62 VHHs as biologics in the context of a respiratory infection is a particularly attractive application,

63 since the highly stable VHHs can be nebulized and administered via an inhaler directly to the site

64 of infection (Respaud et al., 2015). Moreover, due to their stability after prolonged storage,

65 VHHs could be stockpiled as therapeutic treatment options in case of an epidemic. Although

66 therapeutics against MERS-CoV and SARS-CoV-2 are sorely needed, the feasibility of using

67 VHHs for this purpose has not yet been adequately explored. Several MERS-CoV S-directed

68 VHHs have been reported as a result of camelid immunization, but their epitopes remain largely

69   undefined, other than being classified as RBD-directed (Stalin Raj et al., 2018; Zhao et al.,

70   2018).

71   Here we report the isolation of two potently neutralizing VHHs directed against the

72   SARS-CoV-1 and MERS-CoV RBDs, respectively. These VHHs were elicited in response to

73   immunization of a llama with prefusion-stabilized SARS-CoV-1 and MERS-CoV S proteins. We

74   solved the crystal structures of these two VHHs in complex with their respective viral epitopes

75   which suggested likely mechanisms of neutralization were occlusion of the receptor binding

76   interface and trapping of the RBDs in the up conformation. We also show that the SARS-CoV-1

77   RBD-directed VHH cross-reacts with the SARS-CoV-2 RBD and can block the receptor-binding

78   interface. After engineering this VHH into a bivalent Fc-fusion, we show that this cross-reactive

79   VHH can also neutralize SARS-CoV-2 S bearing pseudoviruses. We further demonstrate that the

80   VHH-Fc fusion can be produced at high yields in an industry-standard CHO cell system,

81   suggesting that it merits further investigation as a potential therapeutic for the ongoing COVID-

82   19 pandemic.

83

84   **RESULTS**

85   **Isolation of betacoronavirus S-directed VHHs**

86   Our initial aim was to isolate VHHs that could potently neutralize MERS-CoV and SARS-CoV-

87   1. Therefore, we sequentially immunized a llama subcutaneously twice with SARS-CoV-1 S

88   protein, twice with MERS-CoV S protein, once again with SARS-CoV-1 S and finally with both

89   SARS-CoV-1 and MERS-CoV S protein (**S. Figure 1A**). To obtain VHHs directed against these

90   spike proteins, two consecutive rounds of panning were performed by phage display using either

91   SARS-CoV-1 S or MERS-CoV S protein. Positive clones were sequenced and multiple sequence

92 alignment and phylogenetic analysis using the neighbor-joining method revealed that seven

93 unique MERS-CoV S and five unique SARS-CoV-1 S VHHs were isolated (**S. Figure 1B**).

94 These VHHs and an irrelevant control (RSV F-VHH, directed against the F protein of human

95 respiratory syncytial virus) were subsequently expressed in *Pichia pastoris* and purified from the

96 yeast medium (Rossey et al., 2017). The binding of the purified VHHs to prefusion-stabilized

97 MERS-CoV S and SARS-CoV-1 S was confirmed by ELISA (**S. Figure 1C**). As expected, the

98 irrelevant control had no detectable binding to MERS-CoV S and SARS-CoV-1 S. Four clones

99 (MERS VHH-55, -12, -34 and -40), obtained after panning on MERS-CoV S protein, bound with

100 high affinity to prefusion-stabilized MERS-CoV S, whereas the affinities of VHH-2, -20 and -15

101 were 100- to 1000-fold weaker. Of the five clones isolated after panning on SARS-CoV-1 S

102 protein, three VHH clones (SARS VHH-72, -1 and -6) interacted strongly with prefusion

103 stabilized SARS-CoV-1 S protein. We observed no cross-reactivity of MERS VHHs with SARS-

104 CoV-1 S and vice versa (data not shown).

105 **VHHs neutralize coronavirus S pseudotyped viruses**

106 To assess the antiviral activity of the MERS-CoV and SARS-CoV S-directed VHHs, we

107 performed *in vitro* neutralization assays using MERS-CoV England1 S and SARS-CoV-1 Urbani

108 S pseudotyped lentiviruses. The high affinity MERS VHH-55, -12, -34 and -40 neutralized

109 MERS-CoV S pseudotyped virus with IC_{50} values ranging from 0.014 to 2.9 µg/mL (0.9 nM to

110 193.3 nM), while the lower affinity MERS-CoV or SARS-CoV-1 specific VHHs had no

111 inhibitory effect (**S. Table 1**). SARS VHH-72 and -44 neutralized lentiviruses pseudotyped with

112 SARS-CoV-1 S with IC_{50} values of 0.14 (9 nM) and 5.5 µg/mL (355 nM), respectively. No

113 binding was observed for SARS VHH-44 to prefusion stabilized SARS-CoV-1 S protein in the

114 ELISA assay. Sequence analysis revealed that the neutralizing MERS-CoV specific VHHs -12, -

115   40 and -55 have highly similar complementarity-determining regions (CDRs), indicating that

116   they likely belong to the same clonal family, and may bind to the same epitope (**S. Figure 2**). In

117   contrast, the CDRs from the SARS-CoV S-specific VHHs -44 and -72 are very different.

118   **Mapping domain-specificity of betacoronavirus S-directed VHHs**

119   To map the epitopes targeted by the neutralizing VHHs, we tested binding to recombinant

120   MERS-CoV S1, RBD, and N-terminal domain (NTD) and SARS-CoV-1 RBD and NTD by

121   ELISA (**Figure 1A and S. Figure 3**).The MERS-CoV S-specific VHHs strongly bound to

122   MERS-CoV S1 and RBD in a concentration-dependent manner, and failed to bind to the MERS-

123   CoV NTD. Similarly, strong binding of SARS VHH-72 to the SARS-CoV-1 RBD protein but

124   not the SARS-CoV-1 NTD protein was observed. No binding of SARS VHH-44 to either the

125   SARS-CoV-1 S or NTD protein was detected, leaving the domain that this VHH recognizes

126   undetermined. These data demonstrate that the neutralizing SARS VHH-72 and MERS VHH-55

127   target the RBDs. Based on the specificity and potent neutralizing capacity of SARS VHH-72 and

128   MERS VHH-55, we measured the affinities of these VHHs by immobilizing recombinantly

129   expressed VHH to an SPR sensorchip and determined the binding kinetics for their respective

130   RBDs. We found that both of these VHHs bound to their targets with high affinity. SARS VHH-

131   72 bound to its target with an affinity of 1.2 nM and MERS VHH-55 bound to its target with an

132   affinity of 79.2 pM, in part due to a very slow off-rate constant ($k_d = 8.2 \times 10^{-5}$ s^{-1}) (**Figure 1B**).

133   **Structural basis of VHH interaction with RBDs**

134   To investigate the molecular determinants that mediate potent neutralization and high-affinity

135   binding by MERS VHH-55, we solved the crystal structure of MERS VHH-55 bound to the

136   MERS-CoV RBD. Crystals grew in space group $C222_1$ and diffracted X-rays to a resolution of

137   3.4 Å. After determining a molecular replacement solution and iterative building and refinement,

138   our structure reached an R_{work}/R_{free} of 24.7%/27.8% (**S. Table 2**). The asymmetric unit of this

139   crystal contained eight copies of the MERS VHH-55 + MERS-CoV RBD complex and had a

140   solvent content of ~58%. The electron density allowed unambiguous definition of the interface

141   between the RBD and VHH, with the three CDRs forming extensive binding contacts with the

142   RBD, burying 716 Å^2 of surface area by pinching the RBD between the CDR2 and CDR3. The

143   CDR3 of MERS VHH-55 is looped over the DPP4-binding interface, occluding DPP4 from

144   productively engaging the MERS-CoV RBD (**Figure 2A-B**).

145   There are numerous contacts between the CDRs of MERS VHH-55 and the MERS-CoV

146   RBD; most are confined to CDRs 2 and 3. A network of interactions from all three CDRs

147   (**Figure 2C-D**) suggests that RBD residue Arg542 has a critical role in MERS VHH-55 binding.

148   This arginine has previously been identified as one of the twelve conserved residues that are

149   crucial for high-affinity DPP4 engagement (**S. Figure 4A**) (Wang et al., 2013; Wang et al.,

150   2014).

151   In addition to forming a salt bridge with Glu513 from the MERS-CoV RBD, Trp99 of the

152   MERS VHH-55 CDR3 is positioned near a hydrophobic patch formed by Phe506 (**S. Figure

153   4B**). This residue exhibits natural sequence variation in several MERS-CoV strains, such that a

154   Leu is occasionally observed at this position. To evaluate the extent to which this substitution

155   impacts MERS VHH-55 binding, we generated a F506L substitution and measured binding by

156   SPR (**S. Figure 4C**). This substitution resulted in a ~200-fold reduction in MERS VHH-55

157   binding affinity. Despite this substantial reduction, the affinity of MERS VHH-55 to MERS-CoV

158   RBD F506L remained high, with a $K_D = 16.5$ nM. Other than the variability that is observed at

159   position 506 of the MERS-CoV RBD, the rest of the MERS VHH-55 epitope is highly conserved

160   across the 863 strains that are curated in the MERS-CoV Virus Variation database (**S. Figure

161 **4A**). Despite this predicted broad recognition of MERS-CoV strains, the average sequence

162 identity of 24% between the MERS-CoV RBD and the RBDs from the seasonal coronaviruses

163 HCoV-HKU1, HCoV-OC43, HCoV-229E and HCoV-NL63, makes it unlikely that MERS

164 VHH-55 would cross-react with any of these more distantly related spike proteins.

165   We also sought to discover the molecular determinants of binding between SARS VHH-

166 72 and the SARS-CoV-1 RBD by determining the crystal structure of this complex. Crystals

167 grew in space group $P3_121$ and diffracted X-rays to a resolution of 2.2 Å. We obtained a

168 molecular replacement solution and refined the structure to an R_{work}/R_{free} of 20.3%/23.6%

169 through iterative building and refinement (**S. Table 2**). Our structure reveals that CDRs 2 and 3

170 contribute to most of the 834 Å^2 of buried surface area at the binding interface (**Figure 3A**). This

171 epitope does not, however, overlap with the ACE2 footprint on the SARS-CoV-1 RBD. Rather,

172 ACE2 would clash with the CDR-distal framework of SARS VHH-72, as opposed to classical

173 receptor-blocking in which the CDRs would occupy the ACE2 binding interface (**Figure 3B**).

174 ACE2 also carries an *N*-glycan modification at position Asn322 (Yan, 2020). When bound to the

175 RBD, this *N*-glycan points into the space that is occupied by SARS VHH-72, forming an even

176 larger clash (**Figure 3C**). SARS VHH-72 binds to the SARS-CoV-1 RBD through a hydrogen-

177 bond network involving CDRs 2 and 3, in which backbone groups participate extensively

178 (**Figure3D-E**). This network probably accounts for the high-affinity binding that we observed

179 for these two molecules.

180 **SARS VHH-72 cross-reacts with WIV1-CoV and SARS-CoV-2**

181 Analysis of 10 available SARS-CoV-1 sequences revealed a high degree of conservation in the

182 residues that make up the SARS VHH-72 epitope, prompting us to explore the breadth of SARS

183   VHH-72 binding (**S. Figure 5A**). WIV1-CoV is a betacoronavirus found in bats that is closely

184   related to SARS-CoV-1 and also utilizes ACE2 as a host-cell receptor (Ge et al., 2013). Due to

185   the relatively high degree of sequence conservation between SARS-CoV-1 and WIV1-CoV, we

186   expressed the WIV1-CoV RBD and measured binding to SARS VHH-72 by SPR (**S. Figure**

187   **5B**). SARS VHH-72 exhibited high-affinity binding to the WIV1-CoV RBD (7.4 nM),

188   demonstrating that it cross-reacts with these two closely related coronaviruses (**S. Figure 5C**).

189   Based on the high degree of structural homology that has been reported between SARS-

190   CoV-1 S and SARS-CoV-2 S (Walls, 2020; Wrapp et al., 2020), we also tested SARS VHH-72

191   for cross-reactivity against the SARS-CoV-2 RBD and subdomain 1 (SARS-CoV-2 RBD-SD1)

192   by SPR (**Figure 4**). The equilibrium dissociation constant of SARS VHH-72 for the SARS-CoV-

193   2 RBD-SD1 was ~39 nM, substantially higher than for the SARS-CoV-1 RBD. The weaker

194   binding can primarily be attributed to an increase in the dissociation rate constant (**Figure 4A**).

195   The only variant residue on the SARS-CoV-1 RBD that makes direct contact with SARS VHH-

196   72 is Arg426, which is Asn439 in the SARS-CoV-2 RBD (**Figure 3C**). This mutation prevents

197   the formation of a salt bridge with Asp61 from SARS VHH-72, which likely contributes to the

198   increased dissociation rate constant. Due to an average sequence identity of only 25% between

199   the SARS-CoV-1 RBD and the RBDs of the seasonal coronaviruses, we predict that SARS

200   VHH-72 cross-reactivity is likely confined to the RBD from SARS-CoV-2 and closely related

201   betacoronaviruses such as WIV1-CoV.

202   **VHHs disrupt RBD dynamics and receptor-binding**

203   The RBDs of MERS-CoV S, SARS-CoV-1 S and SARS-CoV-2 S undergo dynamic

204   conformational rearrangements that alternately mask and present their receptor-binding

205   interfaces and potential neutralizing epitopes to host molecules. By aligning the crystal structures

206   of the MERS VHH-55 and SARS VHH-72 complexes to the cryo-EM structures of the MERS-

207   CoV, SARS-CoV-1 and SARS-CoV-2 spike proteins, we can begin to understand how these

208   molecules might function in the context of these dynamic rearrangements. When the MERS-CoV

209   RBDs are all in the down conformation or all in the up conformation, MERS VHH-55 would be

210   able to bind all three of the protomers making up the functional spike trimer without forming any

211   clashes. However, if a down protomer was bound by MERS VHH-55 and the neighboring

212   protomer sampled the up conformation, this RBD would then be trapped in this state by the

213   presence of the neighboring MERS VHH-55 molecule (**Figure 5A**). This conformational

214   trapping would be even more pronounced upon SARS VHH-72 binding to the SARS-CoV-1 S

215   protein or the SARS-CoV-2 S protein. Due to the binding angle of SARS VHH-72, when a

216   bound SARS-CoV-1 or SARS-CoV-2 RBD samples the down conformation, it would clash with

217   the S2 fusion subunit, regardless of the conformations of the neighboring RBDs (**Figure 5B-C**).

218   Therefore, once a single SARS VHH-72 binding event took place, the bound protomer would be

219   trapped in the up conformation until either SARS VHH-72 was released or until the S protein

220   was triggered to undergo the prefusion-to-postfusion transition. Based on the binding angles of

221   MERS VHH-55 and SARS VHH-72, we can conclude that these molecules would likely disrupt

222   the RBD dynamics in the context of a trimeric S protein by trapping the up conformation.

223   Because this up conformation is unstable and leads to S protein triggering, it is possible that this

224   conformational trapping may at least partially contribute to the neutralization mechanisms of

225   these VHHs.

226   To investigate the receptor-blocking ability of the VHHs, we performed a BLI-based

227   assay in which the SARS-CoV-1, SARS-CoV-2 and MERS-CoV RBDs were immobilized to

228   biosensor tips, dipped into VHHs and then dipped into wells containing the recombinant, soluble

229   host cell receptors. We found that when tips coated with the MERS-CoV RBD were dipped into

230   MERS VHH55 before being dipped into DPP4, there was no increase in response that could be

231   attributed to receptor binding. When tips coated with the MERS-CoV RBD were dipped into

232   SARS VHH-72 and then DPP4, a robust response signal was observed, as expected. Similar

233   results were observed when the analogous experiments were performed using the SARS-CoV-1

234   or SARS-CoV-2 RBDs, SARS VHH-72 and ACE2 (**Figure 5D**). These results are consistent

235   with conclusions from our structural analysis that these VHHs can neutralize their respective

236   viral targets by directly interfering with host-cell receptor binding.

237   **Bivalent SARS VHH-72 neutralizes SARS-CoV-2 S pseudoviruses**

238   Despite the relatively high affinity determined by SPR of SARS VHH-72 for the SARS-CoV-2

239   RBD, we could not detect the interaction by ELISA. Moreover, SARS VHH-72 did not

240   neutralize SARS-CoV-2 S VSV pseudoviruses, possibly due to the high dissociation rate

241   constant, although it readily neutralized SARS-CoV-1 pseudotyped reporter viruses (**Figure 6A-**

242   **D**). In an attempt to compensate for this rapid dissociation, we engineered two bivalent variants

243   of SARS VHH-72. These included a tail-to-head fusion of two SARS VHH-72 molecules

244   connected by a (GGGGS)$_3$ linker (VHH-72-VHH-72) and a genetic fusion of SARS VHH-72 to

245   the Fc domain of human IgG1 (VHH-72-Fc) (**S. Figure 6A-C**). These bivalent SARS VHH-72

246   constructs bound to both prefusion SARS-CoV-1 S and SARS-CoV-2 RBD-SD1 as

247   demonstrated by ELISA and by a dose-dependent reduction in the binding of SARS-CoV-2

248   RBD-SD1 to the ACE2 receptor on Vero E6 cells (**Figure 6C-D and S. Figure 6B-C**). We also

249   detected binding of both of these constructs to full length SARS-CoV-1 S and SARS-CoV-2 S

250   expressed on the surface of mammalian cells (**S. Figure 6D-E**). Supernatants of HEK 293S cells

13

251 transiently transfected with VHH-72-Fc exhibited neutralizing activity against both SARS-CoV-

252 1 and SARS-CoV-2 S VSV pseudoviruses in the same assay which showed no such cross-

253 reactive neutralization for monovalent SARS VHH-72 (**Figure 6E-F**). A BLI experiment

254 measuring binding of VHH-72-Fc to immobilized SARS-CoV-2 RBD-SD1 further confirmed

255 that bivalency was able to compensate for the high dissociation constant of the monomer (**Figure**

256 **7A**). Furthermore, the cross-neutralizing VHH-72-Fc construct reached expression levels of

257 ~300 mg/L in ExpiCHO cells (**Figure 7B**). Using VHH-72-Fc purified from ExpiCHO cells and

258 a SARS-CoV-2 S pseudotyped VSV with a luciferase reporter, we evaluated the neutralization

259 capacity of VHH-72-Fc and found that it neutralized pseudovirus with an IC_{50} of approximately

260 0.2 μg/mL (**Figure 7C**).

261 **DISCUSSION**

262 Here we report the isolation and characterization of two potently neutralizing single-domain

263 antibodies from a llama immunized with prefusion-stabilized MERS-CoV and SARS-CoV-1

264 spikes. These VHHs bind to the spike RBDs with high affinity and are capable of neutralizing S

265 pseudotyped viruses *in vitro*. To our knowledge, the isolation and characterization of SARS-

266 CoV-1 S-directed VHHs have not been described before. Several MERS-CoV S-specific VHHs

267 have been described, all of which have been directed against the RBD. Several of these VHHs

268 have also been reported to block DPP4 binding, much like MERS VHH-55 (Stalin Raj et al.,

269 2018; Zhao et al., 2018). By solving the crystal structures of these newly isolated VHHs in

270 complex with their respective viral targets, we provide detailed insights into epitope binding and

271 their mechanisms of neutralization.

272   A number of RBD-directed conventional antibodies have been described that are capable

273 of neutralizing SARS-CoV-1 or MERS-CoV. The epitope of MERS VHH-55 overlaps with the

14

274   epitopes of several of these MERS-CoV RBD-directed antibodies including C2, MCA1, m336,

275   JC57-14, D12, 4C2 and MERS-27 (Chen et al., 2017; Li et al., 2015; Wang et al., 2018; Wang et

276   al., 2015; Ying et al., 2015; Yu et al., 2015) (**S. Figure 7A**). The epitope of SARS VHH-72 does

277   not significantly overlap with the epitopes of any previously described antibodies other than that

278   of the recently described CR3022, which can also bind to the RBDs of both SARS-CoV-1 and

279   SARS-CoV-2 S (Hwang et al., 2006; Pak et al., 2009; Prabakaran et al., 2006; Walls et al., 2019;

280   Yuan M, 2020) (**S. Figure 7B**). However, unlike SARS VHH-72, CR3022 does not prevent the

281   binding of ACE2 and it lacks neutralizing activity against SARS-CoV-2 (Tian et al., 2020; Yuan

282   M, 2020). This discrepancy in function, despite the partially overlapping epitope, is likely due to

283   the different angles of approach that these two antibodies adopt (**S. Figure 7C**). Because SARS

284   VHH-72 binds with a nanomolar K_D to a portion of the SARS-CoV-1 S RBD that exhibits low

285   sequence variation, as demonstrated by its cross-reactivity with the WIV1-CoV and SARS-CoV-

286   2 RBDs, it may broadly bind S proteins from other SARS-CoV-like viruses. We show that by

287   engineering a bivalent VHH-72-Fc construct, we can compensate for the relatively high off-rate

288   constant of the monovalent SARS VHH-72. This bivalent molecule expresses well in transiently

289   transfected ExpiCHO cells (~300 mg/L) and can neutralize SARS-CoV-2 S pseudoviruses *in*

290   *vitro*. Future panning efforts using existing libraries and SARS-CoV-2 S may yield even more

291   potent neutralizers.

292   Due to the inherent thermostability and chemostability of VHHs, they have been

293   investigated as potential therapeutics against several diseases. Several HIV- and influenza-

294   directed VHHs have been reported previously, and there are multiple RSV-directed VHHs that

295   have been evaluated (Detalle et al., 2016; Ibanez et al., 2011; Koch et al., 2017; Rossey et al.,

296   2017). The possibility of administering these molecules via a nebulized spray is particularly

297   attractive in the case of respiratory pathogens because the VHHs could theoretically be inhaled

298   directly to the site of infection in an effort to maximize bioavailability and function (Larios Mora

299   et al., 2018). Due to the current lack of treatments for MERS, SARS and COVID-19 and the

300   devastating effects associated with pandemic coronavirus outbreaks, both prophylactic and

301   therapeutic interventions are sorely needed. It is our hope that due to their favorable biophysical

302   properties and their potent neutralization capacity, MERS VHH-55, SARS VHH-72 and VHH-

303   72-Fc may serve as both useful reagents for researchers and as potential therapeutic candidates.

304

305   **FIGURE LEGENDS**

306   **Figure 1**: Epitope determination and biophysical characterization of MERS VHH-55 and SARS

307   VHH-72. **A**) Reactivity of MERS-CoV and SARS-CoV RBD-directed VHHs against the MERS-

308   CoV and SARS-CoV-1 RBD, respectively. A VHH against an irrelevant antigen (F-VHH) was

309   included as a control. **B**) SPR sensorgrams showing binding between the MERS-CoV RBD and

310   MERS VHH-55 (*left*) and SARS-CoV-1 RBD and SARS VHH-72 (*right*). Binding curves are

311   colored black and fit of the data to a 1:1 binding model is colored red.

312

313   **Figure 2**: The crystal structure of MERS VHH-55 bound to the MERS-CoV RBD. **A**) MERS

314   VHH-55 is shown as blue ribbons and the MERS-CoV RBD is shown as a tan-colored molecular

315   surface. The DPP4 binding interface on the MERS-CoV RBD is colored red. **B**) The structure of

316   DPP4 bound to the MERS-CoV RBD (PDB: 4L72) is aligned to the crystal structure of MERS

317   VHH-55 bound to the MERS-CoV RBD. A single monomer of DPP4 is shown as a red,

318   transparent molecular surface. **C**) A zoomed-in view of the panel from **2A**, with the MERS-CoV

319   RBD now displayed as tan-colored ribbons. Residues that form interactions are shown as sticks,

16

320   with nitrogen atoms colored dark blue and oxygen atoms colored red. Hydrogen-bonds and salt

321   bridges between MERS VHH-55 and the MERS-CoV RBD are shown as black dots. **D**) The

322   same view from **2C** has been turned by approximately 90° to show additional contacts. Residues

323   that form interactions are shown as sticks, with nitrogen atoms colored dark blue and oxygen

324   atoms colored red. Hydrogen-bonds and salt bridges between MERS VHH-55 and the MERS-

325   CoV RBD are shown as black dots.

326

327   **Figure 3**: The crystal structure of SARS VHH-72 bound to the SARS-CoV-1 RBD. **A**) SARS

328   VHH-72 is shown as dark blue ribbons and the SARS-CoV-1 RBD is shown as a pink-colored

329   molecular surface. The ACE2 binding interface on the SARS-CoV-1 RBD is colored red. **B**) The

330   structure of ACE2 bound to the SARS-CoV-1 RBD (PDB: 2AJF) is aligned to the crystal

331   structure of SARS VHH-72 bound to the SARS-CoV-1 RBD. ACE2 is shown as a red,

332   transparent molecular surface. **C**) A simulated *N*-linked glycan containing an energy-minimized

333   trimannosyl core (derived from PDB ID: 1HD4) is modeled as red sticks, coming from Asn322

334   in ACE2. ACE2 is shown as a red molecular surface, the SARS-CoV-1 RBD is shown as pink

335   ribbons and SARS VHH-72 is shown as a dark blue, transparent molecular surface. **D**) A

336   zoomed-in view of the panel from **3A** is shown, with the SARS-CoV-1 RBD now displayed as

337   pink-colored ribbons. Residues that form interactions are shown as sticks, with nitrogen atoms

338   colored dark blue and oxygen atoms colored red. Hydrogen bonds and salt bridges between

339   SARS VHH-72 and the SARS-CoV-1 RBD are shown as black dots. **E**) The same view from **3D**

340   has been turned by 60° to show additional contacts. Residues that form interactions are shown as

341   sticks, with nitrogen atoms colored dark blue and oxygen atoms colored red. Interactions

342   between SARS VHH-72 and the SARS-CoV-1 RBD are shown as black dots.

343

Figure 4: SARS VHH-72 cross-reacts with SARS-CoV-2. **A**) An SPR sensorgram measuring the

binding of SARS VHH-72 to the SARS-CoV-2 RBD-SD1. Binding curves are colored black and

fit of the data to a 1:1 binding model is colored red. **B**) The crystal structure of SARS VHH-72

bound to the SARS-CoV-1 RBD is shown with SARS VHH-72 as dark blue ribbons and the

RBD as a pink molecular surface. Amino acids that vary between SARS-CoV-1 and SARS-CoV-

2 are colored green.

350

Figure 5: Neutralizing mechanisms of MERS VHH-55 and SARS VHH-72. **A**) The MERS-CoV

spike (PDB ID: 5W9H) is shown as a transparent molecular surface, with each monomer colored

either white, gray or tan. Each monomer is bound by MERS VHH-55, shown as blue ribbons.

The clash between MERS VHH-55 bound to the white monomer and the neighboring tan RBD is

highlighted by the red ellipse. **B**) The SARS-CoV-1 spike (PDB ID: 5X58) is shown as a

transparent molecular surface, with each protomer colored either white, gray or pink. Every

monomer is bound by a copy of SARS VHH-72, shown as dark blue ribbons. The clashes

between copies of SARS VHH-72 and the two neighboring spike monomers are highlighted by

the red circle. **C**) The SARS-CoV-2 spike (PDB ID: 6VXX) is shown as a transparent molecular

surface, with each protomer colored either white, gray or green. Every monomer is bound by a

copy of SARS VHH-72, shown as dark blue ribbons. The clashes between copies of SARS

VHH-72 and the two neighboring spike monomers are highlighted by the red circle. The SARS-

CoV-2 trimer appears smaller than SARS-CoV-1 S due to the absence of flexible NTD-distal

loops which could not be built during cryo-EM analysis. **D**) CoV VHHs prevent MERS-CoV

RBD, SARS-CoV-1 RBD and SARS-CoV-2 RBD-SD1 from interacting with their receptors.

18

366   The results of the BLI-based receptor-blocking experiment are shown. The legend lists the

367   immobilized RBDs and the VHHs or receptors that correspond to each curve.

368

369   **Figure 6**: SARS VHH-72 bivalency permits SARS-CoV-2 pseudovirus neutralization. **A**)

370   SARS-CoV-1 S and **B**) SARS-CoV-2 S VSV pseudoviruses were used to evaluate the

371   neutralization capacity of SARS VHH-72. MERS VHH-55 and PBS were included as negative

372   controls. Luciferase activity is reported in counts per second (c.p.s.). NI, cells were not infected.

373   **C**) Binding of bivalent VHHs was tested by ELISA against SARS-CoV-1 S and **D**) SARS-CoV-

374   2 RBD-SD1. VHH-72-Fc refers to SARS VHH-72 fused to a human IgG1 Fc domain by a

375   GS(GGGGS)$_2$ linker. VHH-72-Fc (S) is the same Fc fusion with a GS, rather than a

376   GS(GGGGS)$_2$, linker. GBP is an irrelevant GFP-binding protein. VHH-72-VHH-72 refers to the

377   tail-to-head construct with two SARS VHH-72 proteins connected by a (GGGGS)$_3$ linker. VHH-

378   23-VHH-23 refers to the two irrelevant VHHs linked via the same (GGGGS)$_3$ linker. **E**) SARS-

379   CoV-1 S and **F**) SARS-CoV-2 S pseudoviruses were used to evaluate the neutralization capacity

380   of bivalent VHH-72-Fc. GBP and PBS were included as negative controls. NI, cells were not

381   infected.

382

383   **Figure 7**: VHH-72-Fc neutralizes SARS-CoV-2 S pseudoviruses. **A**) BLI sensorgram measuring

384   apparent binding affinity of VHH-72-Fc to immobilized SARS-CoV-2 RBD-Fc. Binding curves

385   are colored black, buffer-only blanks are colored gray and the fit of the data to a 1:1 binding

386   curve is colored red. **B**) Time course analysis of VHH-72-Fc expression in ExpiCHO cells. Cell

387   culture supernatants of transiently transfected ExpiCHO cells were removed on days 3-7 after

388   transfection (or until cell viability dropped below 75%), as indicated. Two control mAbs were

389 included for comparison, along with the indicated amounts of purified GBP-Fc as a loading

390 control. **C**) SARS-CoV-2 S pseudotyped VSV neutralization assay. Monolayers of Vero E6 cells

391 were infected with pseudoviruses that had been pre-incubated with the mixtures indicated by the

392 legend. The VHH-72-Fc used in this assay was purified after expression in ExpiCHO cells (n =

393 4). VHH-23-Fc is an irrelevant control VHH-Fc (n = 3). NI, cells were not infected. Luciferase

394 activity is reported in counts per second (c.p.s.) ± SEM.

395

396 **SUPPLEMENTAL FIGURE LEGENDS**

397 **Supplementary Figure 1**: CoV VHH immunization and panning. Related to Figure 1. **A**)

398 Schematic depicting the immunization strategy that was used to isolate both SARS-CoV-1 S and

399 MERS-CoV S-directed VHHs from a single llama. The prefusion stabilized SARS-CoV-1 spike

400 is shown in pink and the prefusion stabilized MERS-CoV spike is shown in tan. **B**) Phylogenetic

401 tree of the isolated MERS-CoV and SARS-CoV S-directed VHHs, based on the neighbor joining

402 method. **C**) Reactivity of MERS-CoV and SARS-CoV S-directed VHHs with the prefusion

403 stabilized MERS-CoV S and SARS-CoV-1 S protein, respectively. A VHH against an irrelevant

404 antigen (F-VHH) was included as a control.

405

406 **Supplementary Figure 2**: Sequence alignment of neutralizing SARS-CoV and MERS-CoV S-

407 directed VHHs. Related to Figure 1. Invariant residues are shown as black dots. The CDRs are

408 shown in boxes and Kabat numbering is shown above.

409

410 **Supplementary Figure 3**: Lack of binding of MERS-CoV and SARS-CoV directed VHHs to

411 non-RBD epitopes. Related to Figure 1. ELISA data showing binding of the MERS-CoV specific

20

412   VHHs to the MERS-CoV S1 protein and absence of binding of the MERS-CoV and SARS-CoV

413   specific VHHs against the MERS-CoV NTD and SARS-CoV-1 NTD, respectively. A VHH

414   against an irrelevant antigen (F-VHH) was included as a control.

415

416   **Supplementary Figure 4**: MERS VHH-55 binds to a relatively conserved epitope on the

417   MERS-CoV RBD. Related to Figure 2. A) The crystal structure of MERS VHH-55 bound to the

418   MERS-CoV RBD is shown with MERS VHH-55 in white ribbons and the MERS-CoV RBD as a

419   multicolored molecular surface. More variable residues are shown in warm colors and more

420   conserved residues are shown in cool colors according to the spectrum (*bottom*). Sequence

421   alignments and variability mapping was performed using ConSurf. **B**) The crystal structure of

422   MERS VHH-55 bound to the MERS-CoV RBD is shown as ribbons with MERS VHH-55

423   colored blue and the MERS-CoV RBD colored tan. Phe506 from the MERS-CoV RBD and

424   Trp99 from MERS VHH-55, which are thought to form hydrophobic interactions with one

425   another are shown as sticks surrounded by a transparent molecular surface. **C**) SPR sensorgram

426   measuring the binding of MERS VHH-55 to the naturally occurring MERS-CoV RBD F506L

427   variant. Binding curves are colored black and the fit of the data to a 1:1 binding model is colored

428   red.

429

430   **Supplementary Figure 5**: SARS VHH-72 binds to a broadly conserved epitope on the SARS-

431   CoV-1 RBD. Related to Figure 3. **A**) The crystal structure of SARS VHH-72 bound to the

432   SARS-CoV-1 RBD is shown, with colors corresponding to those of **SFig 4A**. **B**) The crystal

433   structure of SARS VHH-72 bound to the SARS-CoV-1 RBD is shown with SARS VHH-72 as

434   dark blue ribbons and the RBD as a pink molecular surface. Amino acids that vary between

435 SARS-CoV-1 and WIV1-CoV are colored teal. **C**) SPR sensorgram measuring the binding of

436 SARS VHH-72 to the WIV1-CoV RBD. Binding curves are colored black and the fit of the data

437 to a 1:1 binding model is colored red.

438

439 **Supplementary Figure 6**: Engineering a functional bivalent VHH construct. Related to Figure

440 6. **A**) Flow cytometry measuring the binding of the bivalent SARS VHH-72 tail-to-head fusion

441 (VHH-72-VHH-72) to SARS-CoV-1 or SARS-CoV-2 S expressed on the cell surface. VHH-23-

442 VHH-23, a bivalent tail-to-head fusion of an irrelevant nanobody, was included as a negative

443 control. **B**) Binding of SARS-CoV-2 RBD-SD1 to Vero E6 cells is prevented by VHH-72-VHH-

444 72 in a dose-dependent fashion. Binding of SARS-CoV-2 RBD-SD1 to Vero E6 cells was

445 detected by flow cytometry in the presence of the indicated bivalent VHHs (n = 2 except VHH-

446 72-VHH-72 and VHH-23-VHH-23 at 5 µg/ml, n = 5). **C**) Binding of SARS-CoV-2 RBD-SD1 to

447 Vero E6 cells is prevented by bivalent VHH-72-Fc fusion proteins in a dose-dependent fashion.

448 Binding of SARS-CoV-2 RBD-SD1-Fc to Vero E6 cells was detected by flow cytometry in the

449 presence of the indicated constructs and amounts (n = 2 except no RBD, n = 4). **D**) Cell surface

450 binding of SARS VHH-72 to SARS-CoV-1 S. 293T cells were transfected with a GFP

451 expression plasmid together with a SARS-CoV-1 S expression plasmid. Binding of the indicated

452 protein is expressed as the median fluorescent intensity (MFI), measured to detect the His-tagged

453 MERS VHH-55 or SARS VHH-72 or the SARS VHH-72-Fc fusions, of the GFP positive cells

454 divided by the MFI of the GFP negative cells**. E**) Cell surface binding of SARS VHH-72 to

455 SARS-CoV-2. MFI was calculated using the same equation as **S. Figure 6D**.

456

457   **Supplementary Figure 7**: Comparison of the CoV VHH epitopes with known RBD-directed

458   antibodies. Related to Figures 2 and 3. **A**) The structure of MERS VHH-55 bound to the MERS-

459   CoV RBD is shown with MERS VHH-55 as blue ribbons and the MERS-CoV RBD as a white

460   molecular surface. Epitopes from previously reported crystal structures of the MERS-CoV RBD

461   bound by RBD-directed antibodies are shown as colored patches on the MERS-CoV RBD

462   surface. The LCA60 epitope is shown in yellow, the MERS S4 epitope is shown in green, the

463   overlapping C2/MCA1/m336 epitopes are shown in red and the overlapping JC57-

464   14/D12/4C2/MERS-27 epitopes are shown in purple. **B**) The structure of SARS VHH-72 bound

465   to the SARS-CoV-1 RBD is shown with SARS VHH-72 as dark blue ribbons and the SARS-

466   CoV-1 RBD as a white molecular surface. Epitopes from previously reported crystal structures

467   of the SARS-CoV-1 RBD bound by RBD-directed antibodies are shown as colored patches on

468   the SARS-CoV-1 RBD surface. The 80R epitope is shown in blue, the S230 epitope is shown in

469   yellow, the CR3022 epitope is shown in purple and the overlapping m396/F26G19 epitopes are

470   shown in red. **C**) The SARS RBD is shown as a white molecular surface, ACE2 is shown as a

471   transparent red molecular surface, SARS VHH-72 is shown as dark blue ribbons and CR3022

472   Fab is shown as purple ribbons.

473

474   **STAR METHODS**

475

476   **RESOURCE AVAILABILITY**

477   **Lead Contact**

478   Further information and requests for resources and reagents should be directed to and will be

479   fulfilled by the Lead Contact, Jason S. McLellan (jmclellan@austin.utexas.edu).

480 **Materials Availability**

481 Plasmids generated in this study will be made available on request by the Lead Contact with a

482 completed Materials Transfer Agreement (MTA).

483 **Data and Code Availability**

484 The X-ray crystallographic data and atomic models have been deposited at the Protein Data Bank

485 with accession codes PDB: 6WAQ (SARS-CoV-1 RBD bound by SARS VHH-72) and PDB:

486 6WAR (MERS-CoV RBD bound by MERS VHH-55). The sequences of MERS VHH-55 and

487 SARS VHH-72 have been deposited on GenBank under accession numbers MT350283 and

488 MT350284. A list of software used in this study can be found in the Key Resources Table.

489

490 **EXPERIMENTAL MODEL AND SUBJECT DETAILS**

491 **Cell Lines**

492 FreeStyle293F cells (ThermoFisher Scientific) and HEK293-S cells (ThermoFisher Scientific)

493 were cultured in FreeStyle293 expression media (Life Technologies), cultured at 37 °C with 8%

494 CO_2 while shaking at 130 rpm. HEK293-T cells (ATCC) and Vero E6 cells (ATCC) were

495 cultured at 37 °C in the presence of 5% CO_2 in DMEM supplemented with 10% heat-inactivated

496 FBS, 1% penicillin, 1% streptomycin, 2 mM l-glutamine, non-essential amino acids (Invitrogen)

497 and 1 mM sodium pyruvate. Huh7.5 cells (provided by Dr. Deborah R. Taylor) were cultured at

498 37 °C with 8% CO_2 in flasks with DMEM + 10% FBS. ExpiCHO-S cells (Gibco) were cultured

499 at 37 °C with 8% CO_2 while shaking at 130 rpm in ExpiCHO expression media (Gibco). Cells

500 lines were not tested for mycoplasma contamination nor authenticated.

501

502 **METHOD DETAILS**

Llama immunization

Llama immunizations and subsequent VHH library generation were performed by VIB Nanobody

Core as follows. A llama, negative for antibodies against MERS-CoV and SARS-CoV-1 S

glycoprotein, was subcutaneously immunized with approximately 150 μg recombinant SARS-

CoV-1 S-2P protein on days 0, 7, 28 and 150 μg recombinant MERS-CoV S-2P protein on days

14 and 21 and 150 μg of both MERS-CoV S-2P and SARS-CoV-1 S-2P protein on day 35

(Kirchdoerfer et al., 2018; Pallesen et al., 2017). The adjuvant used was Gerbu LQ#3000.

Immunizations and handling of the llama were performed according to directive 2010/63/EU of

the European parliament for the protection of animals used for scientific purposes and approved

by the Ethical Committee for Animal Experiments of the Vrije Universiteit Brussel (permit No.

13-601-1). Blood was collected 5 days after the last immunization for the preparation of

lymphocytes. Total RNA from the peripheral blood lymphocytes was extracted and used as

template for the first strand cDNA synthesis with oligo dT primer. Using this cDNA, the VHH

encoding sequences were amplified by PCR and cloned between the *PstI* and *NotI* sites of the

phagemid vector pMECS. In the pMECS vector, the VHH encoding sequence is followed by a

linker, HA and His$_6$ tag (AAAYPYDVPDYGSHHHHHH). Electro-competent E.coli TG1 cells

were transformed with the recombinant pMECS vector resulting in a VHH library of about 3 x 10^8

independent transformants. The resulting TG1 library stock was then infected with VCS M13

helper phages to obtain a library of VHH-presenting phages.

Isolation of MERS- and SARS-CoV VHH phages

Phages displaying MERS-CoV-specific VHHs were enriched after 2 rounds of biopanning on

20 μg of immobilized MERS-CoV S-2P protein in one well of a microtiter plate (type II, F96

526   Maxisorp, Nuc). For each panning round an uncoated well was used as a negative control. The

527   wells were then washed 5 times with phosphate-buffered saline (PBS) + 0.05% Tween 20 and

528   blocked with SEA BLOCK blocking buffer (Thermo Scientific) in the first panning round and 5%

529   milk powder in PBS in the second panning round. About 10^{11} phages were added to the coated

530   well and incubated for 1 hour at room temperature. Non-specifically bound phages were removed

531   by washing with PBS + 0.05% Tween 20 (10 times in the first panning round and 15 times in the

532   second panning round). The retained phages were eluted with TEA-solution (14% trimethylamine

533   (Sigma) pH 10) and subsequently neutralized with 1 M Tris-HCl pH 8. The collected phages were

534   amplified in exponentially growing *E.coli* TG1 cells, infected with VCS M13 helper phages and

535   subsequently purified using PEG 8,000/NaCl precipitation for the next round of selection.

536   Enrichment after each panning round was determined by infecting TG1 cells with 10-fold serial

537   dilutions of the collected phages after which the bacteria were plated on LB agar plates with

538    $100\,\mu g\,mL^{-1}$ ampicillin and 1% glucose.

539   Phages displaying SARS-CoV-1 directed VHHs were enriched after 2 rounds of

540   biopanning on $20\,\mu g$ of SARS-CoV-1 S-2P protein captured with an anti-foldon antibody

541   (generously provided by Dr. Vicente Mas) in one well of a microtiter plate (type II, F96 Maxisorp,

542   Nuc). Before panning phages were first added to DS-Cav1 protein (McLellan et al., 2013)

543   containing a C-terminal foldon domain, to deplete foldon specific phages. The unbound phages

544   were next added to the coated well. Panning was performed as described above.

545

546   **Periplasmic ELISA to select MERS- and SARS-CoV VHHs**

547   After panning, 45 individual colonies of phage infected bacteria isolated after the first panning

548   round on MERS-CoV S-2P or SARS-CoV-1 S-2P protein and 45 individual colonies isolated after

549   the second panning round on MERS-CoV S-2P or SARS-CoV-1 S-2P protein were randomly

550   selected for further analysis by ELISA for the presence of MERS-CoV and SARS-CoV-1 specific

551   VHHs, respectively. The individual colonies were inoculated in 2 mL of terrific broth (TB)

552   medium with 100 µg/mL ampicillin in 24-well deep well plates. After growing individual colonies

553   for 5 hours at 37 °C, isopropyl β-D-1-thiogalactopyranoside (IPTG) (1 mM) was added to induce

554   VHH expression during overnight incubation at 37 °C. To prepare periplasmic extract, the bacterial

555   cells were pelleted and resuspended in 250 µL TES buffer (0.2 M Tris-HCl pH 8, 0.5 mM EDTA,

556   0.5 M sucrose) and incubated at 4 °C for 30 min. Subsequently 350 µL water was added to induce

557   an osmotic shock. After 1-hour incubation at 4 °C followed by centrifugation, the periplasmic

558   extract was collected.

559   VHH-containing periplasmic extracts were then tested for binding to either MERS-CoV S-

560   2P or SARS-CoV-1 S-2P protein. Briefly, in the PE-ELISA screen after panning on MERS-CoV

561   S-2P protein, wells of microtiter plates (type II, F96 Maxisorp, Nuc) were coated overnight at 37

562   °C with 100 ng MERS-CoV S-2P (without foldon), MERS-CoV S-2P protein (with foldon) or as

563   negative controls coated with SARS-CoV-1 S-2P protein (with foldon), HCoV-HKU1 S-2P

564   (without foldon), DS-Cav1 (with foldon) or bovine serum albumin (BSA, Sigma-Aldrich). In the

565   PE-ELISA screen after panning on SARS-CoV-1 S protein wells of microtiter plates (type II, F96

566   Maxisorp, Nuc) were coated with 100 ng SARS-CoV-1 S-2P protein (with foldon), SARS-CoV-1

567   S-2P protein captured with an anti-foldon antibody (with foldon) or as negative controls coated

568   with MERS-CoV S-2P (without foldon), HCoV-HKU1 S-2P (without foldon), DS-Cav1 (with

569   foldon) or bovine serum albumin (BSA, Sigma-Aldrich). The coated plates were blocked with 5%

570   milk powder in PBS and 50 µL of the periplasmic extract was added to the wells. Bound VHHs

571   were detected with anti-HA (1/2,000, MMS-101P Biolegend) mAb followed by horseradish

572   peroxidase (HRP)-linked anti-mouse IgG (1/2,000, NXA931, GE Healthcare). Periplasmic

573   fractions, for which the OD_{450} value of the antigen coated wells were at least two times higher than

574   the OD_{450} value of the BSA coated wells, were considered to be specific for the coated antigen and

575   selected for sequencing. The selected clones were grown in 3 mL of LB medium with 100 µg/mL

576   ampicillin. The DNA of the selected colonies was isolated using the QIAprep Spin Miniprep kit

577   (Qiagen) and sequenced using the MP057 primer (5'-TTATGCTTCCGGCTCGTATG-3').

578

579   **VHH cloning into a *Pichia pastoris* expression vector**

580   In order to express the MERS- and SARS-CoV VHHs in *Pichia pastoris*, the VHH encoding

581   sequences were cloned in the pKai61 expression vector (described by Schoonooghe *et al.*, 2009)

582   (Schoonooghe et al., 2009). In the vector, the VHH sequences contain a C-terminal 6x His-tag, are

583   under the control of the methanol inducible AOX1 promotor and in frame with a modified version

584   of the *S.cerevisae* α-mating factor prepro signal sequence. The vector contains a Zeocine resistance

585   marker for selection in bacteria as well as in yeast cells. The VHH encoding sequences were

586   amplified by PCR using the following forward and reverse primer (5'-

587   GGCGGGTATCTCTCGAGAAAAGGCAGGTGCAGCTGCAGGAGTCTGGG-3') and (5'-

588   CTAACTAGTCTAGTGATGGTGATGGTGGTGGCTGGAGACGGTGACCTGG-3') and

589   cloned between the *Xho*I and *Spe*I sites in the pKai61 vector. The vectors were linearized by *PmeI*

590   and transformed in the *Pichia pastoris* strain GS115 by electroporation at 1500 V using a Gene

591   Pulser electroporator (Bio-Rad) *(Lin-Cereghino et al., 2005).* After transformation, the yeast cells

592   were plated on YPD plates (1% (w/v) yeast extract, 2% (w/v) peptone, 2% (w/v) dextrose and 2%

593   (w/v) agar) supplemented with zeocin (100 µg/mL) for selection.

594

Generating bivalent VHHs for *P. pastoris* expression

To generate bivalent tandem tail-to-head VHH constructs, the VHH sequence was amplified by PCR using the following forward (5'-GGGGTATCTCTCGAGAAAAGGCAGGTGCAGCTGGTGGAGTCTGGG-3') and reverse (5'-AGACTCCTGCAGCTGCACCTGACTACCGCCGCCTCCAGATCCACCTCCGCCACTACCGCCTCCGCCGCTGGAGACGGTGACCTGGG-3') primers, thereby removing a *Pst*I site from the beginning of the VHH coding sequence and adding a (GGGGS)$_3$ linker and the start of the VHH coding sequence with a *Pst*I site at the end of the sequence. After PCR, the fragment was cloned between the *XhoI* and *SpeI* sites in a SARS VHH-72 containing pKai61 vector, thereby generating a homo-bivalent construct. The vector containing this bivalent VHH was linearized and transformed in GS155 *Pichia pastoris* cells as outlined above.

Purification of MERS- and SARS-CoV VHHs from *Pichia*

The transformed *Pichia pastoris* clones were first expressed in 2 mL cultures. On day 1, 4 clones of each construct were inoculated in 2 mL of YPNG medium (2% pepton, 1% Bacto yeast extract, 1.34% YNB, 0.1 M potassium phosphate pH 6, 0.00004% biotin, 1% glycerol) with 100 µg/mL Zeocin (Life Technologies) and incubated while shaking at 28 °C for 24 hours. The next day, the cells were pelleted by centrifugation and the medium was replaced by YPNM medium (2% pepton, 1% Bacto yeast extract, 1.34% YNB, 0.1 M potassium phosphate pH 6.0, 1% methanol) to induce VHH expression. Cultures were incubated at 28 °C and 50 µL of 50% methanol was added at 16, 24 and 40 h. After 48 h, the yeast cells were pelleted and the supernatant was collected. The presence of soluble VHHs in the supernatants was verified using SDS-PAGE and subsequent

618   Coomassie Blue staining. VHH-containing supernatants of the different clones for each construct

619   were pooled and the VHHs were purified using HisPur^{TM} Ni-NTA Spin Plates (88230, Thermo

620   Scientific™). Next, purified VHHs were concentrated on AcroPrep^{TM} Advance 96-well filter

621   plates for ultrafiltration 3 kDa cutoff (8033,Pall) and the imidazole-containing elution buffer was

622   exchanged with PBS.

623   Production was scaled up (50 mL) for the VHHs with neutralizing capacity. Growth and

624   methanol induction conditions and harvesting of medium were similar as mentioned above for the

625   2 mL cultures. The secreted VHHs in the medium were precipitated by ammonium sulfate

626     $(NH_4)_2SO_4$ precipitation (80% saturation) for 4 h at 4 °C. The insoluble fraction was pelleted by

627   centrifugation at 20,000 g and resuspended in 10 mL binding buffer (20 mM NaH_2PO_4 pH 7.5,

628   0.5M NaCl and 20 mM imidazole pH 7.4). The VHHs were purified from the solution using a 1

629   mL HisTrap HP column (GE Healthcare). To elute the bound VHHs a linear imidazole gradient

630   starting from 20 mM and ending at 500 mM imidazole in binding buffer over a total volume of 20

631   mL was used. VHH containing fractions were pooled and concentrated and the elution buffer was

632   exchanged with PBS with a Vivaspin column (5 kDa cutoff, GE Healthcare).

633

634   **Enzyme-linked immunosorbent assay**

635   Wells of microtiter plates (type II, F96 Maxisorp, Nuc) were coated overnight at 4 °C, respectively,

636   with 100 ng recombinant MERS-CoV S-2P protein (with foldon), SARS-CoV-1 S-2P protein (with

637   foldon), MERS-CoV RBD, MERS-CoV NTD, MERS-CoV S1, SARS-CoV-1 RBD, SARS-CoV-

638   1 NTD or Fc-tagged SARS-CoV-2 RBD-SD1. The coated plates were blocked with 5% milk

639   powder in PBS. Dilution series of the VHHs were added to the wells. Binding was detected by

640   incubating the plates sequentially with either mouse anti-Histidine Tag antibody (MCA1396, Abd

641 Serotec) followed horseradish peroxidase (HRP)-linked anti-mouse IgG (1/2000, NXA931, GE

642 Healthcare) or Streptavidin-HRP (554066, BD Biosciences) or by an HRP-linked rabbit anti-

643 camelid VHH monoclonal antibody (A01861-200, GenScript). After washing 50 µL of TMB

644 substrate (Tetramethylbenzidine, BD OptETA) was added to the plates and the reaction was

645 stopped by addition of 50 µL of 1 M H_2SO4. The absorbance at 450 nM was measured with an

646 iMark Microplate Absorbance Reader (Bio Rad). Curve fitting was performed using nonlinear

647 regression (Graphpad 7.0).

648

649 **CoV pseudovirus neutralization**

650 Pseudovirus neutralization assay methods have been previously described (Pallesen et al., 2017;

651 Wang et al., 2015). Briefly, pseudoviruses expressing spike genes for MERS-CoV England1

652 (GenBank ID: AFY13307) and SARS-CoV-1 Urbani (GenBank ID: AAP13441.1) were

653 produced by co-transfection of plasmids encoding a luciferase reporter, lentivirus backbone, and

654 spike genes in 293T cells (Wang et al., 2015). Serial dilutions of VHHs were mixed with

655 pseudoviruses, incubated for 30 min at room temperature, and then added to previously-plated

656 Huh7.5 cells. 72 hours later, cells were lysed, and relative luciferase activity was measured.

657 Percent neutralization was calculated considering uninfected cells as 100% neutralization and

658 cells transduced with only pseudovirus as 0% neutralization. IC_{50} titers were determined based

659 on sigmoidal nonlinear regression.

660 To generate replication-deficient VSV pseudotyped viruses, HEK293T cells, transfected with

661 MERS-CoV S, SARS-CoV-1 S or SARS-CoV-2 S were inoculated with a replication deficient

662 VSV vector containing eGFP and firefly luciferase expression cassettes. After a 1 hour

663 incubation at 37 °C, inoculum was removed, cells were washed with PBS and incubated in media

664 supplemented with an anti-VSV G mAb (ATCC) for 16 hours. Pseudotyped particles were then

665 harvested and clarified by centrifugation (Berger Rentsch and Zimmer, 2011; Hoffmann, 2020).

666 For the VSV pseudotype neutralization experiments, the pseudoviruses were incubated for 30

667 min at 37 °C with different dilutions of purified VHHs or with dilution series of culture

668 supernatant of 293S cells that had been transfected with plasmids coding for SARS VHH-72

669 fused to human IgG1 Fc (VHH-72-Fc) or with GFP-binding protein (GBP: a VHH specific for

670 GFP). The incubated pseudoviruses were subsequently added to confluent monolayers of Vero

671 E6 cells. Sixteen hours later, the transduction efficiency was quantified by measuring the firefly

672 luciferase activity in cell lysates using the firefly luciferase substrate of the dual-luciferase

673 reporter assay system (Promega) and a Glowmax plate luminometer (Promega).

674

675 **Mammalian protein expression and purification**

676 Mammalian expression plasmids encoding SARS VHH72, MERS VHH55, residues 367-589 of

677 MERS-CoV S (England1 strain), residues 320-502 of SARS-CoV-1 S (Tor2 strain), residues

678 307-510 of WIV1-CoV S, residues 319-591 of SARS-CoV-2 S, residues 1-281 of SARS-CoV-1

679 S (Tor2 strain), residues 1-351 of MERS-CoV S (England1 strain), residues 1-751 of MERS-

680 CoV S (England1 strain), residues 1-1190 of SARS-CoV-1 S (Tor2 strain) with K968P and

681 V969P substitutions (SARS-CoV-1 S-2P), residues 1-1291 of MERS-CoV S (England1 strain)

682 with V1060P and L1061P substitutions (MERS S-2P), residues 1-1208 of SARS-CoV-2 S with

683 K986P and V987P substitutions (SARS-CoV-2 S-2P), residues 1-615 of ACE2 and residues 40-

684 766 of DPP4 were transfected into FreeStyle293 cells using polyethylenimine (PEI). All of these

685 plasmids contained N-terminal signal sequences to ensure secretion into the cell supernatant.

686 Supernatants were harvested and constructs containing C-terminal HRV3C cleavage sites, 8x

687 His-Tags and Twin-Strep-Tags (SARS VHH72, MERS VHH55, MERS-CoV S1, SARS-CoV-1

688 S-2P, MERS-CoV S-2P, SARS-CoV-2 S-2P, ACE2 and DPP4) were purified using Strep-Tactin

689 resin (IBA). Constructs containing C-terminal HRV3C cleavage sites and Fc-tags (SARS-CoV-1

690 RBD, MERS-CoV RBD, WIV1-CoV RBD, SARS-CoV-2 RBD-SD1, SARS-CoV-1 NTD,

691 MERS-CoV NTD) were purified using Protein A resin (Pierce). The SARS-CoV-1 RBD,

692 MERS-CoV RBD, WIV1-CoV RBD, SARS-CoV-2 RBD-SD1, SARS VHH-72, MERS VHH-

693 55, MERS-CoV NTD and SARS-CoV-1 NTD were then further purified using a Superdex 75

694 column (GE Healthcare) in 2 mM Tris pH 8.0, 200 mM NaCl and 0.02% NaN_3. MERS-CoV S1,

695 SARS-CoV-1 S-2P, MERS-CoV S-2P, ACE2 and DPP4 were further purified using a Superose

696 6 column (GE Healthcare) in 2 mM Tris pH 8.0, 200 mM NaCl and 0.02% NaN_3.

697   HEK 293S cells were transfected with VHH-72-Fc or VHH-72-Fc (S) encoding plasmids

698 using PEI. Briefly, suspension-adapted and serum-free HEK 293S cells were seeded at 3 x 10^6

699 cells/mL in Freestyle-293 medium (ThermoFisher Scientific). Next, 4.5 µg of pcDNA3.3-

700 VHH72-Fc plasmid DNA was added to the cells and incubated on a shaking platform at 37 °C

701 and 8% CO_2, for 5 min. Next, 9 µg of PEI was added to the cultures, and cells were further

702 incubated for 5 h, after which an equal culture volume of Ex-Cell-293 (Sigma) was added to the

703 cells. Transfections were incubated for 4 days, after which cells were pelleted (10', 300g) and

704 supernatants were filtered before further use.

705   VHH-72-Fc was expressed in ExpiCHO cells (ThermoFisher Scientific), according to the

706 manufacturer's protocol. Briefly, a 25 mL culture of 6 x10^6 cells/mL, grown at 37 °C and 8%

707 CO_2 was transfected with 20 µg of pcDNA3.3-VHH-72-Fc plasmid DNA using ExpiFectamine

708 CHO reagent. One day after transfection, 150 µL of ExpiCHO enhancer and 4 mL of ExpiCHO

709 feed was added to the cells, and cultures were further incubated at 32 °C and 5% CO_2. Cells were

710 fed a second time 5 days post-transfection. Cultures were harvested as soon as cell viability

711 dropped below 75%. For purification of the VHH-72-Fc, supernatants were loaded on a 5 mL

712 MabSelect SuRe column (GE Healthcare). Unbound proteins were washed away with McIlvaine

713 buffer pH 7.2, and bound proteins were eluted using McIlvaine buffer pH 3. Immediately after

714 elution, protein-containing fractions were neutralized using a saturated Na_3PO_4 buffer. These

715 neutralized fractions were then pooled, and loaded onto a HiPrep Desalting column for buffer

716 exchange into storage buffer (25 mM L-Histidine, 125 mM NaCl).

717

718 **Surface plasmon resonance**

719 His-tagged SARS VHH-72 or MERS VHH-55 was immobilized to a single flow cell of an NTA

720 sensorchip at a level of ~400 response units (RUs) per cycle using a Biacore X100 (GE

721 Healthcare). The chip was doubly regenerated using 0.35 M EDTA and 0.1 M NaOH followed

722 by 0.5 mM $NiCl_2$. Three samples containing only running buffer, composed of 10 mM HEPES

723 pH 8.0, 150 mM NaCl and 0.005% Tween 20, were injected over both ligand and reference flow

724 cells, followed by either SARS-CoV-1 RBD, WIV1-CoV RBD, SARS-CoV-2 RBD-SD1 or

725 MERS-CoV RBD serially diluted from 50-1.56 nM, with a replicate of the 3.1 nM concentration.

726 The resulting data were double-reference subtracted and fit to a 1:1 binding model using the

727 Biacore X100 Evaluation software.

728

729 **Crystallization and data collection**

730 Plasmids encoding for MERS VHH-55 and residues 367-589 of MERS-CoV S with a C-terminal

731 HRV3C cleavage site and a monomeric human Fc tag were co-transfected into kifunensin-treated

732 FreeStyle 293F cells, as described above. After purifying the cell supernatant with Protein A

733 resin, the immobilized complex was treated with HRV3C protease and Endoglycosidase H to

734 remove both tags and glycans. The complex was then purified using a Superdex 75 column in 2

735 mM Tris pH 8.0, 200 mM NaCl and 0.02% NaN_3. The purified complex was then concentrated

736 to 5.0 mg/mL and used to prepare hanging-drop crystallization trays. Crystals grown in 1.0 M

737 Na/K phosphate pH 7.5 were soaked in mother liquor supplemented with 20% ethylene glycol

738 and frozen in liquid nitrogen. Diffraction data were collected to a resolution of 3.40 Å at the SBC

739 beamline 19-ID (APS, Argonne National Laboratory)

740   Plasmids encoding for SARS VHH-72 and residues 320-502 of SARS-CoV-1 S with a C-

741 terminal HRV3C cleavage site and a monomeric human Fc tag were co-transfected into

742 kifunensin-treated FreeStyle 293F cells, as described above. After purifying the cell supernatant

743 with Protein A resin, the immobilized complex was treated with HRV3C protease and

744 Endoglycosidase H to remove both tags and glycans. The processed complex was subjected to

745 size-exclusion chromatography using a Superdex 75 column in 2 mM Tris pH 8.0, 200 mM NaCl

746 and 0.02% NaN_3. The purified complex was then concentrated to 10.0 mg/mL and used to

747 prepare hanging-drop crystallization trays. Crystals grown in 0.1 M Tris pH 8.5, 0.2 M $LiSO_4$,

748 0.1 M LiCl and 8% PEG 8000 were soaked in mother liquor supplemented with 20% glycerol

749 and frozen in liquid nitrogen. Diffraction data were collected to a resolution of 2.20 Å at the SBC

750 beamline 19-ID (APS, Argonne National Laboratory)

751

752 **Structure determination**

753 Diffraction data for both complexes were indexed and integrated using iMOSFLM before being

754 scaled in AIMLESS (Battye et al., 2011; Evans and Murshudov, 2013). The SARS-CoV-1

755 RBD+SARS VHH-72 dataset was phased by molecular replacement in PhaserMR using

756 coordinates from PDBs 2AJF and 5F1O as search ensembles (McCoy, 2007). The MERS-CoV

757 RBD+MERS VHH-55 dataset was also phased by molecular replacement in PhaserMR using

758 coordinates from PDBs 4L72 and 5F1O as search ensembles. The resulting molecular

759 replacement solutions were iteratively rebuilt and refined using Coot, ISOLDE and Phenix

760 (Adams et al., 2002; Croll, 2018; Emsley and Cowtan, 2004). The MERS-CoV+MERS VHH-55

761 structure was refined using NCS. Crystallographic software packages were curated by SBGrid

762 (Morin et al., 2013).

763

764 **Biolayer interferometry**

765 Anti-human capture (AHC) tips (FortéBio) were soaked in running buffer composed of 10 mM

766 HEPES pH 7.5, 150 mM NaCl, 3 mM EDTA, 0.005% Tween 20 and 1 mg/mL BSA for 20 min

767 before being used to capture either Fc-tagged SARS-CoV-1 RBD, Fc-tagged SARS-CoV-2

768 RBD-SD1 or Fc-tagged MERS-CoV RBD to a level of 0.8 nm in an Octet RED96 (FortéBio).

769 Tips were then dipped into either 100 nM MERS VHH-55 or 100 nM SARS VHH-72. Tips were

770 next dipped into wells containing either 1 μM ACE2 or 100 nM DPP4 supplemented with the

771 nanobody that the tip had already been dipped into to ensure continued saturation. Data were

772 reference-subtracted and aligned to each other in Octet Data Analysis software v11.1 (FortéBio)

773 based on a baseline measurement that was taken before being dipped into the final set of wells

774 that contained either ACE2 or DPP4.

775 BLI measurements were also performed with VHH-72-Fc fusion produced in HEK 293S cells.

776 SARS-CoV-2 RBD with a mouse IgG1 Fc tag (Sino Biological) was immobilized to an anti-

777 mouse IgG Fc capture (AMC) tip (FortéBio) to a response level of 0.5 nm. Supernatant of non-

778 transfected and VHH-72-Fc transfected HEK293-S cells was applied in a three-fold dilution

779   series in kinetics buffer. Binding was measured at 30 °C, with baseline and dissociation

780   measured in equal dilution of non-transformed HEK293S supernatant in kinetics buffer. Between

781   analyses, biosensors were regenerated by three times 20 s exposure to regeneration buffer (10

782   mM glycine pH 1.7).

783

784   **Flow cytometry**

785   Binding of VHH-72-Fc, VHH-72-Fc (S) and monomeric and bivalent SARS VHH-72 to SARS-

786   CoV-1 and SARS-CoV-2 S was analyzed by flow cytometry using cells transfected with a GFP

787   expression plasmid combined with an expression plasmid for either SARS-CoV-1 or SARS-Cov-

788   2 S. HEK 293S culture media (1/20 diluted in PBS + 0.5%BSA) of VHH-72-Fc and VHH-72-Fc

789   (S) transformants were incubated with transfected cells. Binding of the VHH-72-Fc and VHH-

790   72-Fc (S) to cells was detected with an AF633 conjugated goat anti-human IgG antibody,

791   whereas binding of monomeric and bivalent VHHs to SARS-CoV-1 or SARS-CoV-2 S was

792   detected with a mouse anti-HisTag antibody and an AF647 conjugated donkey anti-mouse IgG

793   antibody. Binding was calculated as the mean AF633 fluorescence intensity (MFI) of GFP

794   expressing cells (GFP$^+$) divided by the MFI of GFP negative cells (GFP$^-$).

795

796   **RBD competition assay on Vero E6 cells**

797   SARS-CoV-2 RBD fused to murine IgG Fc (Sino Biological) at a final concentration of 0.4

798   μg/mL was incubated with a dilution series of tail-to-head bivalent VHHs or VHH-Fc fusions

799   and incubated at room temperature for 20 min before an additional 10 min incubation on ice.

800   Vero E6 cells grown at sub-confluency were detached by cell dissociation buffer (Sigma) and

801   trypsin treatment. After washing once with PBS the cells were blocked with 1% BSA in PBS on

802   ice. All remaining steps were also performed on ice. The mixtures containing RBD and tail-to-

803 head bivalent VHHs or VHH-Fc fusions were added to the cells and incubated for one hour.

804 Subsequently, the cells were washed 3 times with PBS containing 0.5% BSA and stained with an

805 AF647 conjugated donkey anti-mouse IgG antibody (Invitrogen) for 1 hour. Following

806 additional 3 washes with PBS containing 0.5% BSA, the cells were analyzed by flow cytometry

807 using an BD LSRII flow cytometer (BD Biosciences).

808

809 **QUANTIFICATION AND STATISTICAL ANALYSIS**

810 Binding and neutralization assays were conducted with at least duplicate measurements and

811 presented as the mean ± SEM of the indicated number of replicates. Details can be found in

812 figure legends.

826 support staff of both VIB-IRC and VIB-CMB centers, the members of VIB Discovery Sciences

827 units' COVID-19 team for rapid and consistent support and input. Argonne is operated by

828 UChicago Argonne, LLC, for the US Department of Energy (DOE), Office of Biological and

829 Environmental Research under Contract DE-AC02-06CH11357.

830 **AUTHOR CONTRIBUTIONS**

831 Conceptualization, D.W., D.D.V., B.S.G., B.S., N.C., X.S., and J.S.M.; Investigation and

832 visualization, D.W., D.D.V., K.S.C., G.M.T., N.W., W.V.B., K.R., L.v.S., M.H., S.P., and B.S.;

833 Writing - Original Draft, D.W. and D.D.V.; Writing – Reviewing & Editing, D.W., D.D.V.,

834 K.S.C., G.M.T., N.W., B.S.G., N.C., B.S., X.S., and J.S.M.; Supervision, B.S.G., N.C., B.S.,

835 X.S., and J.S.M.

836 **DECLARATIONS OF INTEREST**

837 K.S.C., N.W., B.S.G. and J.S.M. are inventors on US patent application no. 62/412,703, entitled

838 "Prefusion Coronavirus Spike Proteins and Their Use". D.W., K.S.C., N.W., B.S.G., and J.S.M.

839 are inventors on US patent application no. 62/972,886, entitled "2019-nCoV Vaccine." D.W.,

840 D.D.V., B.S.G., B.S., X.S., and J.S.M. are inventors on US patent application no. 62/988,610,

841 entitled "Coronavirus Binders". D.W., N.C., B.S., X.S., and J.S.M. are inventors on US patent

842 application no. 62/991,408, entitled "SARS-CoV-2 Virus Binders".
